

# An $\mathrm{SL}_2(k)$ Character Variety Whose Dimension Jumps in Characteristic 2

Ben Martin

September 25, 2002

## 1 Introduction

In this note we give an example of a finitely generated group  $\Gamma$  such that:

(I) there exists a field  $\Omega$  of characteristic 2 with a discrete valuation  $\nu_0$  and a representation  $\rho_0: \Gamma \rightarrow \mathrm{SL}_2(\Omega)$  such that the induced action of  $\Gamma$  on the Bruhat-Tits tree of  $\mathrm{SL}_2(\Omega)$  is fixed-point free;

(II) for every field  $K$  of characteristic zero with a discrete valuation, no homomorphism  $\rho: \Gamma \rightarrow \mathrm{SL}_2(K)$  gives rise to a fixed-point free action of  $\Gamma$  on the Bruhat-Tits tree of  $\mathrm{SL}_2(K)$ . In particular,  $\Gamma$  admits no ANI-representations.

For terminology and background discussion, see [SZ].

If  $\Gamma$  were the fundamental group of a compact 3-manifold  $M$  then  $\rho_0$  would give an essential surface in  $M$  that is not detectable by the method of ANI representations or by looking at ideal points of curves in the character variety  $\mathrm{C}(\Gamma, \mathrm{SL}_2(\mathbb{C}))$ . I do not know whether such a 3-manifold exists for this particular choice of  $\Gamma$ , but perhaps a similar example can be constructed for appropriate  $M$ .

## 2 Character Varieties

Let  $F$  be a finitely generated group and let  $k$  be an algebraically closed field. We consider representations (i.e. group homomorphisms) of  $F$  into  $\mathrm{SL}_2(k)$ . Below,  $T \subset \mathrm{SL}_2(k)$  denotes the group of diagonal matrices.

The set  $\mathrm{R}(F, \mathrm{SL}_2(k))$  of representations (i.e. group homomorphisms)  $\rho: F \rightarrow \mathrm{SL}_2(k)$  has the structure of an affine variety over  $k$ . The group  $\mathrm{SL}_2(k)$  acts on

$R(F, \mathrm{SL}_2(k))$  by conjugation:  $(D.\rho)(\gamma) := D\rho(\gamma)D^{-1}$ . Since  $\mathrm{SL}_2(k)$  is a reductive algebraic group, we have a well-defined quotient variety  $C(F, \mathrm{SL}_2(k))$ , the points of which correspond to Zariski-closed conjugacy classes of representations. By results of R. W. Richardson, the conjugacy class of a representation  $\rho$  is closed if and only if  $\rho$  is completely reducible. Clearly  $\rho$  is completely reducible if and only if either  $\rho(F)$  lies in some conjugate of  $T$  or  $\rho$  is irreducible. The co-ordinate ring of the affine variety  $C(F, \mathrm{SL}_2(k))$  is the ring of conjugation-invariant regular functions on  $R(F, \mathrm{SL}_2(k))$ . One way to obtain such a function is as follows: given  $\gamma \in \Gamma$ , define  $\mathrm{Tr}_\gamma: R(\Gamma, \mathrm{SL}_2(k)) \rightarrow k$  by  $\mathrm{Tr}_\gamma(\rho) = \mathrm{Tr} \rho(\gamma) = \chi_\rho(\gamma)$ , where  $\mathrm{Tr}$  denotes trace and  $\chi_\rho: \Gamma \rightarrow k$  is the character of  $\rho$ . We denote by  $\pi$  the canonical map from  $R(F, \mathrm{SL}_2(k))$  to  $C(F, \mathrm{SL}_2(k))$ .

The rest of this section is not essential for Section 3. Let  $\mathcal{S}$  be the  $k$ -algebra generated by functions of the form  $\mathrm{Tr}_\gamma$ , a subring of the co-ordinate ring of  $C(\Gamma, \mathrm{SL}_2(k))$ . If  $\mathcal{S}$  is finitely generated as a  $k$ -algebra then  $\mathcal{S}$  is the co-ordinate ring of an affine variety  $X(F, \mathrm{SL}_2(k))$ , and we have a dominant map  $\psi: C(F, \mathrm{SL}_2(k)) \rightarrow X(F, \mathrm{SL}_2(k))$ . It is known that if  $k = \mathbb{C}$  then  $\mathcal{S}$  is indeed finitely generated and  $\psi$  is an isomorphism (hence the name “character variety” or “variety of characters” for  $C(F, \mathrm{SL}_2(k))$ ). For general  $k$  it follows from results of Donkin that  $\mathcal{S}$  is a finitely generated  $k$ -algebra and the map  $\psi$  is finite (see [M], Theorem 1.4); note that any regular conjugation-invariant function on  $\mathrm{SL}_2(k)$  is a polynomial in  $\mathrm{Tr}$ .

**Conjecture 2.1** *The map  $\psi$  is an isomorphism.*

### 3 The Example

Let  $\Gamma$  be the group with presentation

$$\Gamma = \langle a, b, c \mid a^2 = b^2 = c^2 = 1, [b, cac] = [b, aca] = 1, cac = aca \rangle.$$

Note that  $a, c$  generate a copy of the symmetric group  $S_3$ . We show that:

- (a) if the characteristic of  $k$  is not 2 then the variety  $C(\Gamma, \mathrm{SL}_2(k))$  is finite, and for every  $\rho \in R(\Gamma, \mathrm{SL}_2(k))$ ,  $\rho(\Gamma)$  is finite;
- (b) if  $k$  has characteristic 2 then  $X(\Gamma, \mathrm{SL}_2(k))$  is infinite: in particular,  $C(\Gamma, \mathrm{SL}_2(k))$  is infinite and there exists an affine curve in  $C(\Gamma, \mathrm{SL}_2(k))$  with an ideal point. (Applying the construction described in [SZ] now gives the field  $\Omega$ , the discrete valuation  $\nu_0$  and the representation  $\rho_0$  of (I) above.)

Because a finite group acting without inversions on a tree must fix a vertex ([S], I.6, Example 3.1), (a) implies (II) above.

Assume that the characteristic of  $k$  is not 2. Let  $\rho: \Gamma \rightarrow \mathrm{SL}_2(k)$  be any completely reducible representation. Set  $A = \rho(a), B = \rho(b), C = \rho(c)$ . The hypothesis on the characteristic implies that  $A, B, C \in \pm I$ , and part (a) follows.

Now assume that  $k$  has characteristic 2. For  $\mu \in k$ , define  $\rho_\mu: \Gamma \rightarrow \mathrm{SL}_2(k)$  by

$$\rho(a) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \rho(b) = \begin{pmatrix} 1 & \mu \\ 0 & 1 \end{pmatrix}, \rho(c) = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix}.$$

We have

$$\rho(c)\rho(a)\rho(c) = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix},$$

and

$$\rho(a)\rho(c)\rho(a) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix},$$

so  $\rho$  is well-defined. Now  $\mathrm{Tr}_{bc}(\rho_\mu) = \mathrm{Tr}(\rho_\mu(bc)) = \mu$ , so the function  $\mathrm{Tr}_{bc}$  takes on infinitely many values. It follows that  $X(\Gamma, \mathrm{SL}_2(k))$  is infinite, as required.
